Exchange Rate

- Centralized: ask/bid, sell/buy, the last trade, e.g., 200 DAI for 1 ETH → price (order book)
 - Prince changes if trade happens, ask was same or lower than bid. Ask/bid submitted by users
 - Slippage: you see a price, submit, and until its executed, price can change.
 - Set limits, order may stay in the orderbook
- Order/time important \rightarrow frontrunning, more data stored on chain
- Decentralized: ratio of pairs (automatic market making)
 - Slippage: the "same" sometimes (mis)used as price impact
 - Example amount in pool: DAI 200, ETH 1 \rightarrow price 200DAI/1ETH
- Large swap can change price (as with CEX)

2 Blockchain

Exchange Rate / Decentralized Swaps

- To not drain pool, Uniswap uses X * Y = k, where k is constant, X and Y are asset values (if you take out X you need to provide Y)
 - DAI = 200, ETH = 1, k = 200
- Constant function market makers (CFMM)
 - We are still very early in the evolution of constant function market makers [ref]
- Simple exchange price calculation (Uniswap)
 - Swap for 0.5 ETH, if you send 0.5 ETH to pool
 - 200/1.5 \rightarrow 133 DAI \rightarrow $~\sim 133$ DAI for 1 ETH
 - Deduct 66 DAI from pool \rightarrow 133/1.5 \rightarrow \sim 88 DAI for 1 ETH
 - k=133.333 * 1.5 = 200
 - Not draining the pool, but trading with better price than resulting pool

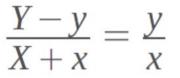

- x is input asset amount (ETH)
 X is input asset balance (ETH)
 y is output asset amount (DAI)
- Y is output asset balance (DAI)

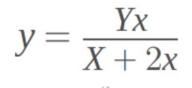

Exchange Rate / Decentralized Swaps

- Reverse of 133/1.5 \rightarrow I want to buy ETH with 66 DAI
 - 133+66/1.5 at price 133.333 → 66/133 = 0.5 ETH (new price 200DAI/ETH)
- If swap price should be == the final pool price
 - Similar to Uniswap, but the trade will happen exactly at the price of the resulting pool price
 - Example 200*0.5/(1+2*0.5) = 50
 - 150/1.5 = 50/0.5
 - However, reverse: from 150 DAI/1.5 ETH → y=0.3, results in 200 DAI/1.2ETH, new price 166DAI/ETH. To get the same price (200), need to swap 75 DAI for 0.375ETH → 225/1.125ETH

x is input asset amount (ETH)
X is input asset balance (ETH)
y is output asset amount (DAI)
Y is output asset balance (DAI)

Decentralized Swap

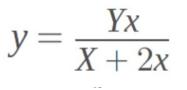

- Swap 0.5 ETH for DAI, how much DAI? (price 200DAI/ETH)
- (price 133DAI/ETH), but DAI funds not decreased yet
- How much do you get?
- Fixed formula, y=50, bought 50 DAI for 0.5ETH (price 100DAI/ETH)

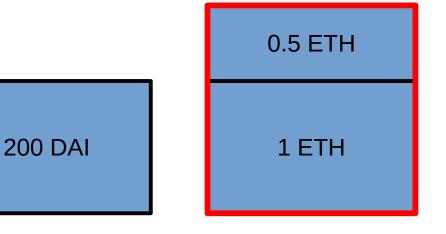

200-y DAI

• Pool: 150 DAI, 1.5 ETH, price (100DAI/ETH)

50

150 DAI

Decentralized Swap

- Many AMM variations
 - THORChain punish large swaps [how its calculated]
 - Example: 0.5 * 200 * 1 / (0.5 + 1)^2 = 44.4 (price 88DAI/1ETH)
 - Resulting pool: 155.555/1.5 \rightarrow price 103.7DAI/1ETH
 - Large trades gives you a worse rate than the resulting pool price. Small values, e.g., 0.1 ETH \rightarrow 16.5DAI / 165DAI/ETH, pool: 166.8DAI/ETH
- More AMMs, here
- Attacks: Exploit slippage tolerance: sandwich attack (frontrunning) [seen in practice]

- x is input asset amount (ETH)
- X is input asset balance (ETH)
- y is output asset amount (DAI)
- Y is output asset balance (DAI)

 $y = \frac{xYX}{(x+X)^2}$

AMM Fundamentals

- Swaps (just covered)
- Arbitrage bots
 - Swapping in multiple pools or CEX, if a boot sees e.g., a trading opportunity,
 - Example: Pool 1: 250 DAI for 1 ETH, pool 1: 200 DAI for 1 ETH
 - Buy for 1 ETH 250 DAI in pool 1, go to pool 2 and sell 250 DAI for 1.25 ETH, profit = 0.25 ETH
- Liquidity providers (LP)
 - Filling the pools
 - General rules for AMM-based DEX: providing / removing liquidity does not change the price
 - LP provide 50/50 ratio of assets, example with a 200DAI/1ETH pool
 - LP can provide 100DAI/0.5ETH, or 400DAI/2ETH

Liquidity Providing

- Why should a LP provide liquidity?
 - The LP receives an LP token (ERC20) \rightarrow % of the liquidity provided in the pool
 - E.g., LP provides 20DAI/0.1ETH \rightarrow LP tokens says its 10% of the pool
 - Adding / removing liquidity from others affects my pool percentage. Eg., more liquidity provided, the 10% will be decreased.
 - For each swap, user has to pay fees
 - Fees are distributed proportionally to the amount of LP tokens
 - Eg., fees collected are 2ETH, LP gets 10%, 0.2ETH
 - Earn fees for providing liquidity
- With LP token, you can back the 10% (or less if liquidity was added) of pool assets + accumulated fees

Liquidity Providing

- Why is not everybody liquidity providing?
 - Impermanent Loss (its mostly permanent)
 - "Users who provide liquidity to AMMs can see their staked tokens lose value compared to simply holding the tokens on their own."
 - 200 DAI (price 1\$), 1 ETH (price 200\$) → \$40 (10%)
 - ETH price goes up 300\$, hodler: 50\$ (10%)
 - − Arbitration, 1 ETH can be bought for 200\$ in this pool and sold for 300\$ \rightarrow provide 45 Dai, get 0.19 ETH
 - Uniswap formula: 245DAI/0.81ETH \$49 (10%) 1\$ loss instead hodling
 - The more volatile the market is the higher the impermanent loss
 - Uniswap V3, to reduce the impermanent loss risk, provide liquidity within certain price ranges
 - My previously used formula: Pool: 250DAI/0.8333ETH 50\$ (10%)? $y = \frac{Y_X}{X + 2y}$

$$y = \frac{Yx}{X+x}$$

Liquidity Providing (Liquidity Mining)

- LP Token: fees + impermanent loss
 - Other incentive staking: if you place your token in a staking contract
 - Staking != staking
 - Staking on the blockchain layer: proof of funds to mine blocks (ETH 2, Cardano)
 - Staking in contracts: remove liquidity (supply) from the market to influence the price, as a reward, get more tokens (any tokens, e.g., governance tokens – token economics)
- Liquidity mining = yield farming
 - A protocol chooses e.g., the best LP with highest APY automatically (e.g., yearn)
 - Optimize crypto assets earnings through lending and trading services [ref]
 - CRV Curve Token \rightarrow Curve AMM smart contract
