CEX: Exchange Rate

- Centralized (CEX): ask/bid, sell/buy, the last trade, e.g., 200
 DAI for 1 ETH → price (order book)
 - Workflow: create order, publish on exchange, wait to get filled.
 Browse orders, start fill order.
 - Prince changes if trade happens, ask was same or lower than bid.
 Ask/bid submitted by users add/remove orders
 - Slippage: you see a price, submit, and until its executed, price can change.
 - Set limits, order may stay in the orderbook
- Decentralized (DEX): ratio of pairs (automatic market making)
 - Workflow: exchange pairs
 - Example amount in pool: DAI 200, ETH 1 → price 200DAI/1ETH
- Both: large swap can change price → price impact

DEX: Exchange Rate / Decentralized Swaps

- DEX uses X * Y = k, where k is constant, X and Y are asset values (if you take out X you need to provide Y)
 - DAI = 200, ETH = 1, k = 200
- Constant function market makers (CFMM)
 - "We are still very early in the evolution of constant function market makers..." [ref]
- Exchange price calculation $(X * Y = k) \rightarrow X * Y = (X + x) * (Y y)$
 - Swap for 0.5 ETH, if you send 0.5 ETH to pool

$$-$$
 66/0.5 → 133 DAI → ~**133 DAI for 1 ETH**

- Deduct 66 DAI from pool, add 0.5 ETH \rightarrow 133/1.5 \rightarrow ~ 88 DAI for 1 ETH
 - K = 133.333 * 1.5 = 200
 - Never draining the pool
 - Trade with better price than resulting pool (huge price impact)

```
x is input asset amount (ETH)
X is input asset balance (ETH)
y is output asset amount (DAI)
Y is output asset balance (DAI)
```

Exchange Rate / Decentralized Swaps

- Reverse of 133/1.5 \rightarrow I want to buy ETH with 66 DAI
 - 1.5*66/(133+66) = 0.5 $x = \frac{Xy}{Y+y}$
 - Swap at price 133.333 → new price 200DAI/ETH → reversible
- If swap price == the final pool price

$$\frac{Y-y}{X+x} = \frac{y}{x} \qquad y = \frac{Yx}{X+2x}$$
• Example 200 5.6/(1+2*...)

- - 150/1.5 = 50/0.5 (swap and final price the same)
- However, not reversible with same numbers. To get the same price (200), need to swap 75 DAI for 0.375ETH \rightarrow 225/1.125ETH
- THORChain

$$y = \frac{xYX}{(x+X)^2}$$

x is input asset amount (ETH) X is input asset balance (ETH) y is output asset amount (DAI) Y is output asset balance (DAI)

Decentralized Swap

- Many AMM variations
 - THORChain punish large swaps [how its calculated]
 - Example: 0.5 * 200 * 1 / (0.5 + 1)^2 = 44.4 (price 88DAI/1ETH)
 - Resulting pool: 155.555/1.5 → price 103.7DAI/1ETH
 - Large trades gives you a worse rate than the resulting pool price. Small values, e.g., 0.1 ETH → 16.5DAI / 165DAI/ETH, pool: 166.8DAI/ETH
- More AMMs, here
- Attacks: Exploit slippage tolerance: sandwich attack (frontrunning) [seen in practice]

```
x is input asset amount (ETH)
X is input asset balance (ETH)
y is output asset amount (DAI)
Y is output asset balance (DAI)
```

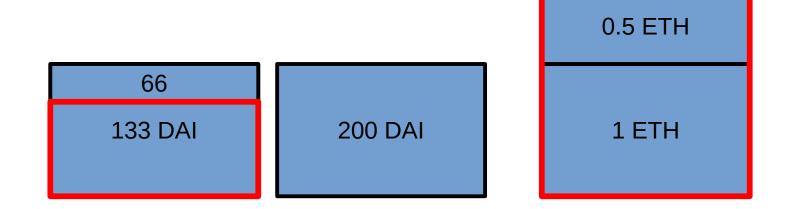

$$y = \frac{xYX}{(x+X)^2}$$

Decentralized Swap

- Swap 0.5 ETH for DAI, how much DAI? (price 200DAI/ETH)
- (price 133DAI/ETH), but DAI funds not decreased yet
- Pool: 133 DAI, 1.5 ETH, price (88DAI/ETH)

$$y = \frac{Yx}{X + x}$$

DeFi Fundamentals

- Swaps (just covered)
- Arbitrage bots
 - Swapping in multiple pools or CEX, if a boot sees e.g., a trading opportunity,
 - Example: Pool 1: 250 DAI for 1 ETH, pool 2: 200
 DAI for 1 ETH
 - Arbitrage bot has 1 ETH (not considering price impact in this example)
 - Buy for 1 ETH 250 DAI in pool 1
 - Sell 250 DAI for 1.25 ETH in pool 2, profit = 0.25 ETH
 - Keep the same price across exchanges

- Flash loans
 - Same chain: arbitrage bots can use flash loans
 - Get loan and pay it back in the same transaction
 - No risk for lender, either he gets the tokens back or transaction is invalid
- Example with Aave: from 1000 to 1045, including payback of 1000.9
 - SushiSwap, Uniswap, DAI, wETH
- Without arbitrage bots, DEX does not work!
 - Essential part of the ecosystem

DeFi Fundamentals

- Swaps (just covered)
- Arbitrage bots (just covered)
- Liquidity providers (LP)
 - Someone should provide liquidity filling the pools
 - General rules for AMM-based DEX
 - Providing / removing liquidity no change of price
 - LP provide 50/50 ratio of assets, example with a 200DAI/1ETH pool
 - LP can provide 100DAI/0.5ETH, or 400DAI/2ETH
 - LP_a gets liquidity units (LP token), with 100/0.5 (new pool: 300/1.5), LP_a owns 1/3 of the pool
- Why should a LP provide liquidity?

Liquidity Providing

- LP token → % of the liquidity provided in the pool
 - Earn fees for providing liquidity
 - For each swap, user has to pay fees
 - Fees are distributed proportionally to the amount of LP tokens
 - Eg., fees collected are 2ETH, LP gets 10%, 0.2ETH
 - More liquidity provided by others, the 10% will be decreased → less earnings

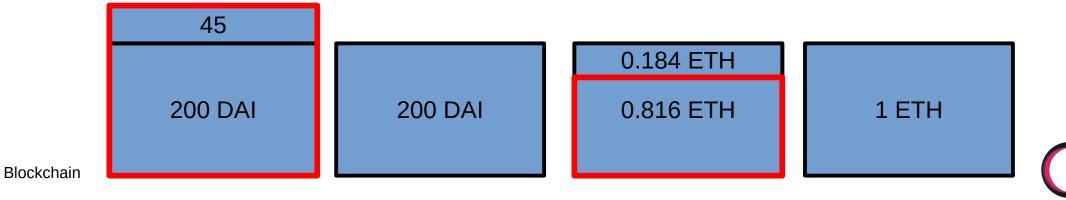

- Why is not everyone providing liquidity?
 - Free money?

Liquidity Providing

- Impermanent Loss (its mostly permanent, better name: price shift loss)
 - "Users who provide liquidity to AMMs can see their staked tokens lose value compared to simply holding the tokens on their own."
 - Example: I own 10% of the pool: 200 DAI (price 1\$), 1 ETH (price 200\$)
 - 20 DAI, 0.1 ETH (\$20) \rightarrow \$40
 - ETH price goes up 300\$, hodler:
 - 20 DAI, 0.1 ETH (\$30) \rightarrow \$50
 - Pool is at 200/1, other pools are at $300/1 \rightarrow \text{arbitration}$

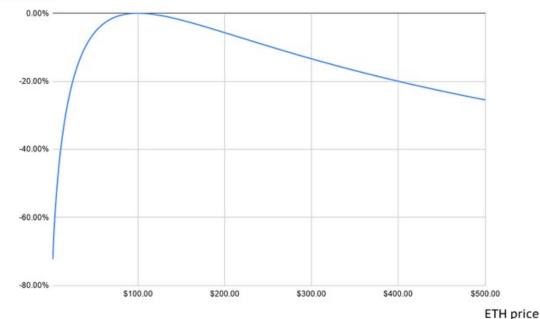

$$y = \frac{Yx}{X + x}$$

Liquidity Providing

- Uniswap formula: ~245DAI/0.8166
 - 10% of 245 DAI → \$24.5
 - 10% of 0.8166 ETH → 0.08166 ETH (\$24.5)
- \$49 vs \$50 1\$ loss instead hodling
 - The more volatile the market is the higher the impermanent loss
- LP Token: fees + impermanent loss
 - Other incentive staking: if you place your token in a staking or yield farming contract

Impermanent Loss

Lets use a DEX

- SushiSwap
 - ClassicAMM → v3 introduces concentrated liquidity, which makes the impermanent loss situation better, but introduces complexity
 - UniswapV2Router02.sol
 - UniswapV2Factory.sol
 - Sepolia, V2Factory
 - Sepolia, V2Router02
